TIS WEBINAR

FROM DEVELOPOR TO CEO

The perfect Blend of Technology and Business

"What do you do today?" "Where does it become slow or difficult?"

INTRODUCTION

NAME OF SPEAKER

Assoc. Prof. Dr. Hj. Mohamad Hafiz Izran bin Ishak

EXECUTIVE SUMMARY

A talk from Assoc. Prof. Dr. Hj. Mohamad Hafiz Izran bin Ishak about AR Mechatronics PLT, their product **MyREDS**, business management and operation. Other than that, the speaker also explains the **difference of perspective** between a **developer and a CEO** and summarization on **developing a product** and **forming a company**

REFLECTION

The webinar has enlighten me that business career is far more acheivable than what I imagine. Even if one's amibition does not involve business, it is a wise idea for us to always remember there is still **alternative paths** other than becoming a employee.

As intimdating as the idea of owning a business, it is very much achiveable, especially with the **rise in use of AI** in many sectors including business. To own a business, one important trait one must have is **being bold** — the ability to **steps out of the comfort zone** to try new things — and that is essentially what makes us differ from simply being a CEO to an outstanding CEO.

MINDSET & LEADERSHIP (DEVELOPER TO CEO)

Core Shift:

Code performance *"Does it work?"* → Business sustainability *"Can we keep delivering it?"*

Leadership & Ownership:
Extending beyond programming by assigning clear individual accountability for tasks.

Priorities & Cash Discipline:
Aligning team roles, schedules, and managing operational costs to maintain financial health.

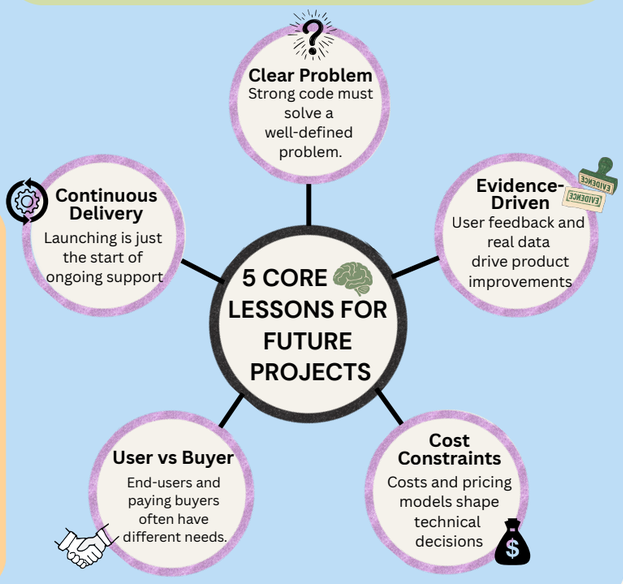

REFLECTION

Reflecting on Dr. Hafis's sharing, I realized that writing clean, bug-free code is only a baseline requirement in real-world software engineering. The core question "*Your app works. Who will pay for it?*" highlighted that **technology must align with clear user problems and business sustainability**.
Furthermore, while AI tools like ChatGPT or Gemini only accelerate prototyping, **human ownership remains essential** for system architecture, validation, and user trust. As a computer science student, this talk inspired me to look beyond technical syntax and adopt a holistic product mindset, **balancing code performance with user value.**

AI ASSISTANCE NEEDS HUMAN OWNERSHIP

AI Assistance:	Human Ownership:
AI tools act as thinking partners for prototyping, debugging, and test generation.	Humans maintain full accountability for architecture, validation, security, and operational reliability.

TIS IN PRACTICE : MyREDS

From **those question**, we developed practical TIS ventures...

→ **MyREDS**, Digital defect counter, eBencana / e-Bantuan, GeoTrees collaborations etc.....

Case Study : ***How do we run a TIS business?***

Ex: **MyREDS** (short for Resident Easy Decison Making System) consists of Resident app/Guard app/Web admin dashboard, has **5 TIS component**

Component | MyREDS Case		| Business Value
People:	Residents/Guard	| User onboarding
Hardware:	Gadget/ Gates	| Setup and repair
Software:	Apps and dashboard	| System maintenance
Data:	Access logs and report	| Cybersecurity
Process:	User Enrolment	| Long-term viability

However, the needs of user and buyer could be different

Stakeholder	| Core Need	| Purchase Focus
Resident:	Fast Tasks	| Feedback
Visitor:	Entry Guide	| First impression
Guard:	Reliable choice	| Training
Management:	Audit & control	| Budget and renewal

MyREDS: 5-Step Visitor Access Journey

1. **Residents** Create an invitation for **Visitor**
2. **Visitor** obtained QR pass or link
3. **Verified access by Guards**
4. **Gate Operation : Allow / Deny Entry**
5. **Management : Monitor operations and record**

Product Scope First Useful Release
A minimum viable product lets a real user finish a meaningful task)
Ex: In the first test:
- **Invitation and QR delivery**
- **Verification and recovery**
- **A usable access record**

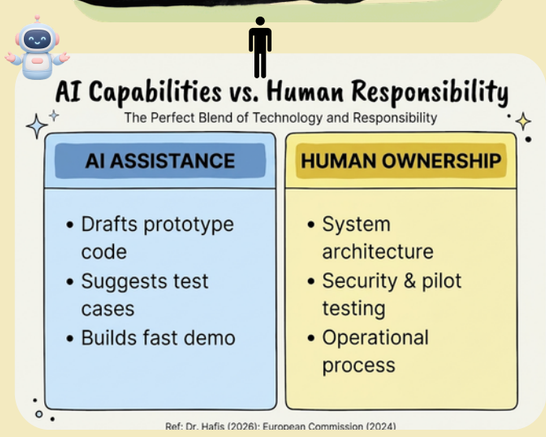

Reflection

This webinar gave me a clear workflow on how to translate theoretical TIS frameworks into real-life practical architecture. By breaking down the 5 TIS components, I realized that building reliable software must take into consideration hardware robustness, data privacy, and transparent processes as well—a TIS business solution does not solely depend on software itself.

Other than that, by analyzing the needs of both the buyer and the user, it showed me that building digital trust in security features is key to **enhancing the perceived value delivered to end-users (Sartono et al., 2024)**. Mutual understanding between stakeholders is essential in ensuring the viability of each component, especially to achieve alignment and agreement.

BUSINESS &REVENUE MODEL

1. **Subscription Fee**: Monthly or annual service plans.
2. **Implementation Fees**: One-time training, setup, and onboarding costs.
3. **Hardware & Maintenance**: Device sales, installation, and maintenance fees.
4. **Customization**: Extra charges for client-specific features.

COST, OPERATIONAL TESTING & POST-SALE DELIVERY

1. **Technical Costs**: Balance development costs and cloud hosting to break even.
2. **Pilot Testing**: Evaluate usability and renewal intent before launch.
3. **Post-Sale Support**: Ongoing maintenance, updates, and contingency solutions.

REFLECTION

From this seminar, I learnt that building a successful business requires far more than product development. It needs careful planning of unique selling points, business models , pilot testing, and continuous maintenance to ensure long term buyer subscription.
Furthermore, AI can improve productivity, but it cannot take the place of human supervision. Humans still responsible for deliverable quality, fundamental system architecture, and efficient communication, as highlighted in study on responsible AI (European Commission, 2024). Thus, ICT professionals remain essential for driving real-world operational ownership and trust.

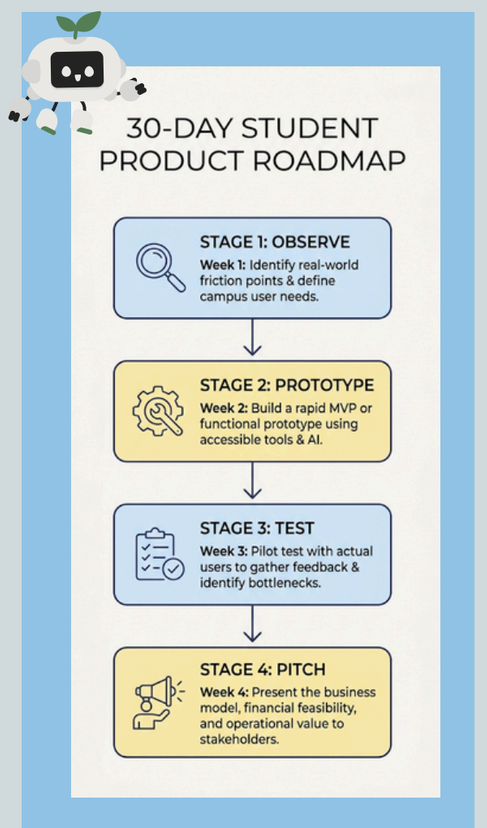

CAMPUS INNOVATION & 30-DAY ROADMAP

- **Framework Overview:** The 30-Day Student Roadmap translates technology into real-world solutions through a 4-phase process: Observe, Prototype, Test, and Pitch.
- **Campus Problem Solving**: Enables students to solve real campus issues (e.g., hostel visitor clearance, parking optimization, facility booking) by focusing on real user friction points.
- **Rapid Execution**: Demonstrates that meaningful technological solutions do not require months of coding; rapid validation and user-centric design yield high-impact outcomes.

REFLECTION

From this talk, I learned that driving innovation **does not always require months of complex software development**; rather, it demands **structured execution** and a **clear problem-solving mindset**. The 30-Day Student Roadmap inspired me to apply **structured product development** (Observe →→ Prototype →→ Test →→ Pitch) directly to our university projects and daily campus challenges.

Furthermore, consolidating our team's poster content highlighted that ICT professionals must **blend technical functionality** with **user-centric design** and **business feasibility**. Mastering this balance empowers developers to **transform simple campus projects into scalable**, **real-world solutions.**
